15.4.3 Relative Stability: Gain and Phase Margins

Why do we need to do all this work and obtain just stability results from Nyquist plots? Why not just use the Routh-Hurwitz criteria?

The real value of the Nyquist plot lies in the fact that it shows how close the system is to instability. For example, let us consider the first example we had.

\[ G(j\omega) = \frac{k}{j\omega(j\omega + 1)^2} \]

For which the Nyquist plot was such that As \( k \) increases, the curve \( \Gamma \) approaches \(-1\). When \( k \) is such that \( (k > 2) \), \( \Gamma \) encircles the point \(-1\), and the closed-loop system becomes unstable. Look at the figure below:

![Figure 15.23: Effect of increasing k on the Nyquist plot](image)
Gain Margin: The gain margin is the factor by which the gain $|G(j\omega)|$ needs to be increased for the closed-loop system to be neutrally stable. The gain margin (GM) is defined as:

$$GM = |G(j\omega_{\text{180\degree}})|^{-1}$$

where, $\omega_{\text{180\degree}}$ is such that $\angle G(j\omega_{\text{180\degree}}) = 180\degree$. The gain margin is normally expressed in dB.

Phase Margin: Phase margin (PM) is the amount by which the phase of $G(j\omega)$ exceeds $180\degree$ when $|G(j\omega)| = 1$. It is defined as,

$$PM = \angle G(j\omega_c) - 180\degree$$

where, the frequency $\omega_c$ is such that $|G(j\omega_c)| = 1$. It is also called the phase cross-over frequency.

Application to Design

Assume a stable open-loop system. Then,

$GM > 0$ (in dB) $\Rightarrow$ Closed-loop system is stable.

$GM > 6$ dB is good $\Rightarrow$ You can double the gain without the system becoming unstable.

$PM > 30\degree$ is good (Note that $PM = 0\degree$ $\Rightarrow$ denotes neutrally stable).

For unstable open loop system, PM and GM can give confusing results.
GM and PM from Bode Plot

GM and PM tells you how much uncertainty one can tolerate in the open loop system before the closed loop system goes to instability.

Phase margin is related to closed loop damping ratio and so to the overshoot. To show this, consider an open loop system,

\[
G_{ol}(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s} = \frac{\omega_n^2}{s(s + 2\zeta\omega_n)}
\]

which produces the closed loop system (with unity feedback and unity gain),

\[
G_{cl}(s) = \frac{\omega_n^2}{s^2 + 2\zeta\omega_n s + \omega_n^2}
\]

Getting back to the open loop system,

\[
|G(j\omega)| = \frac{\omega_n^2}{\sqrt{\omega^4 + 4\zeta^2}\omega_n^2\omega^2}
\]

Find \(\omega_c\), the crossover frequency.

\[
|G(j\omega_c)| = 1
\]

\[
\Rightarrow \omega_c^4 = \omega_n^4 + 4\zeta^2\omega_n^2\omega_c^2
\]

\[
\Rightarrow \omega_c = \omega_n \left[\sqrt{1 + 4\zeta^4 - 2\zeta^2}\right]^{1/2}
\]
Now, find the phase margin as follows,

\[
PM = \tan^{-1}\left[\frac{-\Im(G(j\omega))}{-\Re(G(j\omega))}\right]_{\omega=\omega_c}
\]

\[
= \tan^{-1}\left[\frac{\Im(G(j\omega))}{\Re(G(j\omega))}\right]_{\omega=\omega_c}
\]

Now,

\[
G(j\omega) = \frac{-\omega_n^2}{\omega^2 - j2\zeta\omega_n\omega} = \frac{-\omega_n^2(\omega^2 + j2\zeta\omega_n\omega)}{\omega^4 - 2\zeta^2\omega_n^2\omega^2}
\]

So,

\[
PM = \tan^{-1}\left(\frac{2\zeta\omega_n\omega_c}{\omega_n^2}\right) = \tan^{-1}\left(\frac{2\zeta\omega_n}{\omega_c}\right)
\]

\[
= \tan^{-1}\left[\frac{2\zeta}{\sqrt{\zeta^4 + 2\zeta^2}}\right]
\]

Plotting the PM vs. \(\zeta\), we will get,

![Figure 15.26: PM vs. \(\zeta\)](image-url)
So,
Small PM $\Rightarrow$ small $\zeta$ $\Rightarrow$ large overshoot (but fast response).
Large PM $\Rightarrow$ large $\zeta$ small overshoot (but slow response).
One can come up with design procedure in the frequency domain too. We omit the
details.

**PROBLEM SET 9**

1. Sketch the Nyquist plots for the following loop transfer functions. Find out $N, P,$ and $Z$ and determine if the closed loop system is stable. If yes, then for what values of $K(s) = k$ is the system stable?
   (a) 
   \[ G(s) = \frac{20}{s(1 + 0.1s)(1 + 0.5s)} \]
   (b) 
   \[ G(s) = \frac{3(s + 2)}{s^3 + 3s + 1} \]
   (c) 
   \[ G(s) = \frac{100}{s(s + 1)(s^2 + 2)} \]

2. Let the open loop transfer function be given by
   \[ G(s) = \frac{k}{(s + 1)^n} \]
   Consider $n = 2, 3, 4$ and find out the range of $k$ for which the closed loop system is stable, using Nyquist plot.

3. For all the systems above sketch the Bode plots.

4. For all the systems above determine the phase and gain margins if they are relevant.

5. Check all the results using MATLAB.
