Module 2

Analysis of Statically Indeterminate Structures by the Matrix Force Method

Version 2 CE IIT, Kharagpur
Lesson 13

The Three-Moment Equations-II

Version 2 CE IIT, Kharagpur
Instructional Objectives

After reading this chapter the student will be able to
1. Derive three-moment equations for a continuous beam with yielding supports.
2. Write compatibility equations of a continuous beam in terms of three moments.
4. Analyse continuous beams having different moments of inertia in different spans and undergoing support settlements using three-moment equations.

13.1 Introduction

In the last lesson, three-moment equations were developed for continuous beams with unyielding supports. As discussed earlier, the support may settle by unequal amount during the lifetime of the structure. Such future unequal settlement induces extra stresses in statically indeterminate beams. Hence, one needs to consider these settlements in the analysis. The three-moment equations developed in the previous lesson could be easily extended to account for the support yielding. In the next section three-moment equations are derived considering the support settlements. In the end, few problems are solved to illustrate the method.

13.2 Derivation of Three-Moment Equation

Consider a two span of a continuous beam loaded as shown in Fig.13.1. Let $M_L$, $M_C$ and $M_R$ be the support moments at left, center and right supports respectively. As stated in the previous lesson, the moments are taken to be positive when they cause tension at the bottom fibers. $I_L$ and $I_R$ denote moment of inertia of left and right span respectively and $L_L$ and $L_R$ denote left and right spans respectively. Let $\delta_L, \delta_C$ and $\delta_R$ be the support settlements of left, centre and right supports respectively. $\delta_L, \delta_C$ and $\delta_R$ are taken as negative if the settlement is downwards. The tangent to the elastic curve at support $C$ makes an angle $\theta_{CL}$ at left support and $\theta_{CR}$ at the right support as shown in Fig. 13.1. From the figure it is observed that,
The rotations $\beta_{CL}$ and $\beta_{CR}$ due to external loads and support moments are calculated from the $\frac{M}{EI}$ diagram. They are (see lesson 12)

$$\beta_{CL} = \frac{A_L x_L}{EI_L l_L} + \frac{M_L l_L}{6EI_L} + \frac{M_C l_L}{3EI_L}$$  \hspace{1cm} (13.2a)$$

$$\beta_{CR} = \frac{A_R x_R}{EI_R l_R} + \frac{M_R l_R}{6EI_R} + \frac{M_C l_R}{3EI_R}$$  \hspace{1cm} (13.2b)$$

The rotations of the chord $L'C'$ and $C'R'$ from the original position is given by

$$\alpha_{CL} = \frac{\delta_L - \delta_C}{l_L}$$  \hspace{1cm} (13.3a)$$

$$\alpha_{CR} = \frac{\delta_R - \delta_C}{l_R}$$  \hspace{1cm} (13.3b)$$

From Fig. 13.1, one could write,
Thus, from equations (13.1) and (13.4), one could write,

\[ \dot{\theta}_{\text{cl}} = \alpha_{\text{cl}} - \beta_{\text{cl}} \quad (13.4a) \]

\[ \dot{\theta}_{\text{cr}} = \beta_{\text{cr}} - \alpha_{\text{cr}} \quad (13.4b) \]

Substituting the values of \( \alpha_{\text{cl}}, \alpha_{\text{cr}}, \beta_{\text{cl}} \) and \( \beta_{\text{cr}} \) in the above equation,

\[
M_L \left( \frac{l_L}{l_L} \right) + 2M_C \left( \frac{l_L + l_R}{l_L} \right) + M_R \left( \frac{l_R}{l_R} \right) = -6A_R \frac{x_R}{l_R} - 6A_L \frac{x_L}{l_L} + 6E \left( \frac{\delta_L - \delta_C}{l_L} \right) + 6E \left( \frac{\delta_R - \delta_C}{l_R} \right)
\]

This may be written as

\[
M_L \left( \frac{l_L}{l_L} \right) + 2M_C \left( \frac{l_L + l_R}{l_L} \right) + M_R \left( \frac{l_R}{l_R} \right) = -6A_R \frac{x_R}{l_R} - 6A_L \frac{x_L}{l_L} - 6E \left[ \left( \frac{\delta_C - \delta_L}{l_L} \right) + \left( \frac{\delta_C - \delta_R}{l_R} \right) \right]
\]

(13.6)

The above equation relates the redundant support moments at three successive spans with the applied loading on the adjacent spans and the support settlements.

**Example 13.1**

Draw the bending moment diagram of a continuous beam \( BC \) shown in Fig.13.2a by three moment equations. The support \( B \) settles by 5mm below \( A \) and \( C \). Also evaluate reactions at \( A \), \( B \) and \( C \). Assume \( EI \) to be constant for all members and \( E = 200 \text{ GPa}, I = 8 \times 10^6 \text{ mm}^4 \).
Assume an imaginary span having infinitely large moment of inertia and arbitrary span \( L' \) left of \( A \) as shown in Fig.13.2b. Also it is observed that moment at \( C \) is zero.
The given problem is statically indeterminate to the second degree. The moments $M_A$ and $M_B$, the redundants need to be evaluated. Applying three moment equation to the span $A'AB$,

$$\delta_L = \delta_C = 0 \text{ and } \delta_R = -5 \times 10^{-3} \text{ m}$$

$$M'_A \left( \frac{L'}{\infty} \right) + 2M_A \left( \frac{L'}{\infty} + \frac{4}{I} \right) + M_B \left( \frac{4}{I} \right) = -\frac{6 \times 8 \times 2}{I(4)} - 6E \left( 0 + \frac{0 - (-5 \times 10^{-3})}{4} \right)$$

$$8M_A + 4M_B = -24 - 6EI \times \frac{5 \times 10^{-3}}{4} \quad (1)$$

Note that, $EI = 200 \times 10^9 \times \frac{8 \times 10^6 \times 10^{-12}}{10^3} = 1.6 \times 10^3 \text{ kNm}^2$

Thus,

$$8M_A + 4M_B = -24 - 6 \times 1.6 \times 10^3 \times \frac{5 \times 10^{-3}}{4}$$

$$8M_A + 4M_B = -36 \quad (2)$$

Again applying three moment equation to span $ABC$ the other equations is obtained. For this case, $\delta_L = 0$, $\delta_C = -5 \times 10^{-3} \text{ m}$ (negative as the settlement is downwards) and $\delta_R = 0$.

$$M_A \left[ \frac{4}{I} \right] + 2M_B \left[ \frac{4}{I} + \frac{4}{I} \right] = -\frac{24}{I} - \frac{6 \times 10.667 \times 2}{I \times 4} - 6E \left( \frac{-5 \times 10^{-3}}{4} - \frac{5 \times 10^{-3}}{4} \right)$$

$$4M_A + 16M_B = -24 - 32 + 6 \times 1.6 \times 10^3 \times \frac{10 \times 10^3}{4}$$

$$4M_A + 16M_B = -32 \quad (3)$$

Solving equations (2) and (3),

$$M_B = -1.0 \text{ kN.m}$$

$$M_A = -4.0 \text{ kN.m} \quad (4)$$

Now, reactions are calculated from equations of static equilibrium (see Fig.13.2c).
Thus, 

\[ R_A = 2.75 \text{kN (↑)} \]
\[ R_{BL} = 1.25 \text{kN (↑)} \]
\[ R_{BR} = 4.25 \text{kN (↑)} \]
\[ R_C = 3.75 \text{kN (↑)} \]

The reactions at B,
\[ R_B = R_{BR} + R_{BL} = 5.5 \text{kN} \] (5)

The area of each segment of the shear force diagram for the given continuous beam is also indicated in the above diagram. This could be used to verify the previously computed moments. For example, the area of the shear force diagram between A and B is \( 5.5 \text{kN.m} \). This must be equal to the change in the bending moment between A and D, which is indeed the case (\(-4 - 1.5 = 5.5 \text{kN.m}\)). Thus, moments previously calculated are correct.

**Example 13.2**

A continuous beam \( ABCD \) is supported on springs at supports \( B \) and \( C \) as shown in Fig.13.3a. The loading is also shown in the figure. The stiffness of springs is \( k_B = \frac{EI}{20} \) and \( k_C = \frac{EI}{30} \). Evaluate support reactions and draw bending moment diagram. Assume \( EI \) to be constant.
In the given problem it is required to evaluate bending moments at supports $B$ and $C$. By inspection it is observed that the support moments at $A$ and $D$ are zero. Since the continuous beam is supported on springs at $A$ and $D$, the support settles. Let $R_B$ and $R_C$ be the reactions at $B$ and $C$ respectively. Then the support settlement at $B$ and $C$ are $\frac{R_B}{k_B}$ and $\frac{R_C}{k_C}$ respectively. Both the settlements are negative and in other words they move downwards. Thus,

$$
\delta_A = 0, \quad \delta_B = \frac{-20R_B}{EI}, \quad \delta_C = \frac{-30R_C}{EI} \quad \text{and} \quad \delta_D = 0
$$

(1)
Now applying three moment equations to span $ABC$ (see Fig.13.2b)

$$M_A \left\{ \frac{4}{I} \right\} + 2M_B \left\{ \frac{4}{I} + \frac{4}{I} \right\} + M_C \left\{ \frac{4}{I} \right\} = -\frac{6 \times 21.33 \times 2}{I \times 4} - \frac{6 \times 20 \times 2}{I \times 4} - 6E \left[ -\frac{20R_B}{4EI} + \frac{30R_C}{4EI} \right]$$

Simplifying,

$$16M_B + 4M_C = -124 + 60R_B - 45R_C \quad (2)$$

Again applying three moment equation to adjacent spans $BC$ and $CD$,

$$M_B \left\{ \frac{4}{I} \right\} + 2M_C \left\{ \frac{4}{I} + \frac{4}{I} \right\} = -\frac{60}{I} - \frac{(6 \times 9 \times 2 + 6 \times 3 \times \frac{2}{3} \times 1)}{I \times 4} - 6E \left[ -\frac{30R_C}{EI} + \frac{20R_B}{EI} - \frac{30R_C}{4EI} \right]$$

$$4M_B + 16M_C = -90 + 90R_C - 30R_B \quad (3)$$

In equation (2) and (3) express $R_B$ and $R_C$ in terms of $M_B$ and $M_C$ (see Fig.13.2c)

$$R_A = 8 + 0.25M_B \quad (\uparrow)$$

$$R_{BL} = 8 - 0.25M_B \quad (\uparrow)$$

$$R_{BR} = 5 + 0.25M_C - 0.25M_B \quad (\uparrow)$$

$$R_{CL} = 5 + 0.25M_B - 0.25M_C \quad (\uparrow)$$

$$R_{CR} = 2 - 0.25M_C \quad (\uparrow)$$

$$R_D = 6 + 0.25M_C \quad (\uparrow)$$

Note that initially all reactions are assumed to act in the positive direction (i.e. upwards). Now,

$$R_B = R_{BL} + R_{BR} = 13 - 0.5M_B + 0.25M_C$$

$$R_C = R_{CL} + R_{CR} = 7 + 0.25M_B - 0.5M_C \quad (5)$$

Now substituting the values of $R_B$ and $R_C$ in equations (2) and (3),

$$16M_B + 4M_C = -124 + 60(13 - 0.5M_B + 0.25M_C) - 45(7 + 0.25M_B - 0.5M_C)$$
Or,

\[ 57.25M_B - 33.5M_C = 341 \]  \hspace{1cm} (6)

And from equation 3,

\[ 4M_B + 16M_C = -90 + 90(7 + 0.25M_B - 0.5M_C) - 30(13 - 0.5M_B + 0.25M_C) \]

Simplifying,

\[ -33.5M_B + 68.5M_C = 150 \]  \hspace{1cm} (7)

Solving equations (6) and (7)

\[ M_C = 7.147 \text{ kN.m} \]
\[ M_B = 10.138 \text{ kN.m} \]  \hspace{1cm} (8)

Substituting the values of \( M_B \) and \( M_C \) in (4), reactions are obtained.

\[ R_A = 10.535 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_{BL} = 5.465 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_{BR} = 4.252 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_{CL} = 5.748 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_{CR} = 0.213 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_D = 7.787 \text{ kN} \]  \hspace{1cm} (↑)
\[ R_B = 9.717 \text{ kN} \]  \hspace{1cm} (↑) and \[ R_C = 5.961 \text{ kN} \]  \hspace{1cm} (↑)

The shear force and bending moment diagram are shown in Fig. 13.2d.
Fig. 13.2 (c) Free-body diagram of two members

Shear force diagram

Bending moment diagram

Fig. 13.2(d) Shear force and bending moment diagram
Example 13.3

Sketch the deflected shape of the continuous beam ABC of example 13.1. The redundant moments $M_A$ and $M_B$ for this problem have already been computed in problem 13.1. They are,

$$M_B = -1.0 \text{ kN.m}$$
$$M_A = -4.0 \text{ kN.m}$$

The computed reactions are also shown in Fig.13.2c. Now to sketch the deformed shape of the beam it is required to compute rotations at $B$ and $C$. These joints rotations are computed from equations (13.2) and (13.3).

For calculating $\theta_A$, consider span $A'AB$

$$\theta_A = \beta_{AR} - \alpha_{AR}$$

$$= \frac{A_R \bar{x}_R}{EI_R l_R} + \frac{M_B l_R}{6EI_R} + \frac{M_A l_R}{3EI_R} - \left( \frac{\delta_B - \delta_A}{4} \right)$$

$$= \frac{6 \times 8 \times 2}{1.6 \times 10^3 \times 4} + \frac{M_B \times 4}{1.6 \times 10^3 \times 6} + \frac{M_A \times 4}{1.6 \times 10^3 \times 3} - \left( \frac{\delta_B - \delta_A}{4} \right)$$

$$= \frac{6 \times 8 \times 2}{1.6 \times 10^3 \times 4} + \left( \frac{-1}{1.6 \times 10^3 \times 6} \right) + \left( \frac{-4}{1.6 \times 10^3 \times 3} \right) + \left( \frac{5 \times 10^{-3}}{4} \right)$$

$$= 0 \quad (1)$$

For calculating $\theta_{BL}$, consider span $ABC$

$$\theta_{BL} = \alpha_{BL} - \beta_{BL}$$

$$= \left( \frac{A_L \bar{x}_L}{EI_L l_L} + \frac{M_A l_L}{6EI_L} + \frac{M_B l_L}{3EI_L} \right) + \left( \frac{\delta_A - \delta_B}{l_L} \right)$$

$$= \left( \frac{8 \times 2}{1.6 \times 10^3 \times 4} + \frac{-4 \times 4}{1.6 \times 10^3 \times 6} + \frac{(1) \times 4}{1.6 \times 10^3 \times 3} \right) + \left( \frac{5 \times 10^{-3}}{4} \right)$$

$$= 1.25 \times 10^{-3} \text{ radians} \quad (2)$$

For $\theta_{BR}$ consider span $ABC$
\[
\theta_{br} = \left( \frac{10.67 \times 2}{1.6 \times 10^3 \times 4} + \frac{(-1) \times 4}{1.6 \times 10^3 \times 3} \right) - \left( 0 + \frac{5 \times 10^3}{4} \right)
\]

\[= -1.25 \times 10^{-3} \text{ radians} \tag{3}\]

\[
\theta_c = -\left( \frac{10.67 \times 2}{1.6 \times 10^3 \times 4} + \frac{(-1) \times 4}{1.6 \times 10^3 \times 3} \right) - \left( \frac{\delta_b - \delta_c}{4} \right)
\]

\[= -3.75 \times 10^{-3} \text{ radians}. \tag{4}\]

The deflected shape of the beam is shown in Fig. 13.4.

Summary

The continuous beams with unyielding supports are analysed using three-moment equations in the last lesson. In this lesson, the three-moment-equations developed in the previous lesson are extended to account for the support settlements. The three-moment equations are derived for the case of a continuous beam having different moment of inertia in different spans. Few examples are derived to illustrate the procedure of analysing continuous beams undergoing support settlements using three-moment equations.
